October 2020

#DataBeyondVision

[doi:10.5281/zenodo.3713671](https://doi.org/10.5281/zenodo.3713671)

How do we represent tangible objects in a visual medium? We use words, pictures, and diagrams. We describe, share, show, and fail.

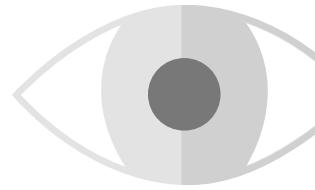

Humanists continue to expand the range of objects they study, but the range of scholarly outputs has not seen a similar expansion. While there are movements within Digital Humanities to consider nontraditional formats, the presentation and publishing of these experimental works (such as installations and project demos) is still secondary or sidelined, where it exists at all. What would it look like to consider non-textual research outputs as first-order scholarly work? The historian David Staley suggests the terms “interpretive objects” or “humanistic objects” for creative scholarly acts that are not limited to text¹; Catherine D’Ignazio and Lauren Klein offer the broader term “rhetorical objects.”² Innovative work like this is carefully researched and theorized. It deserves scholarly engagement and intellectual rigor even if it does not fit into established modes of scholarly communication.

Academic research has a long history of textual practice and citation that we haven’t yet figured out how to adapt to non-textual scholarship. The [Journal of Open Humanities Data](#) and The [Journal of Open Source Software](#) can both be seen as steps in this direction: they provide venues for the review and publication of data and software, respectively, accompanied by brief “metapapers.” But even these rely on transforming the content they review—data and software—into text in order to function! What are the implications if we truly expand the range of accepted scholarly outputs to include such interpretive objects as data structures, databases, software, datasets, physical objects, and augmented reality experiences? Will scholars need to become experts in all these modes, or can we find a way to become conversant in multiple forms of argumentation, as with other important scholarly theories?

The pieces that follow describe four different data physicalizations, which we consider to be one class of interpretive object. This is an exploration of our work as we wrestle with how to present physical objects in a non-physical medium, objects meant to be held, touched, or viewed from different angles. Not quite metapaper, manual, or manifesto — these are guides towards reading and thinking in creative new scholarly modes.³

SEE

from a distance.
Cold, commanding.
Sense of mastery,
but optical illusions deceive.

Look in a mirror.
and see yourself
seeing.

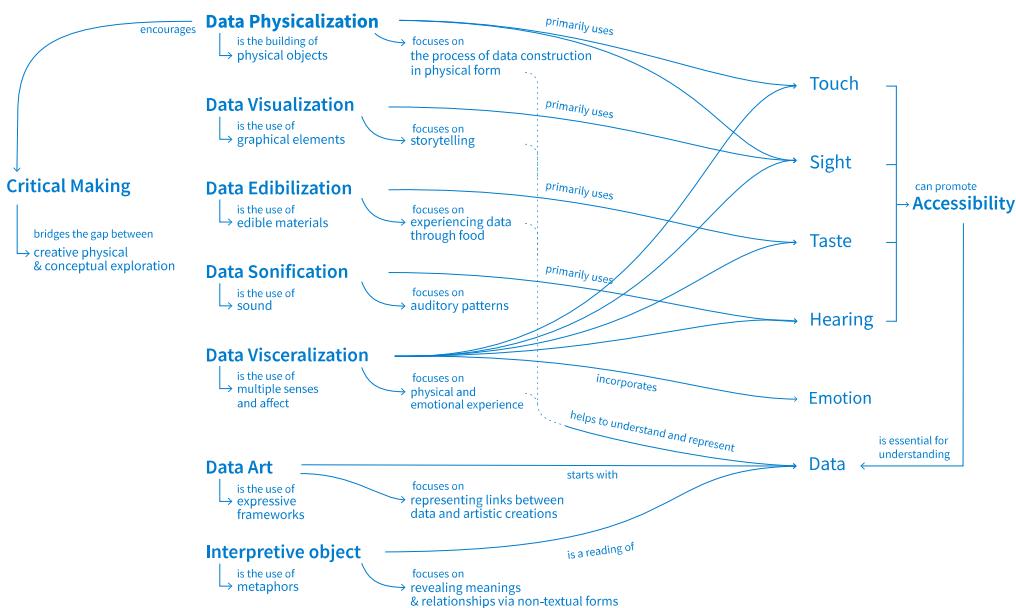

**TOUCH**

up close.
Intimate, incomplete.
Explore partial knowledge,
enlighten slowly.

Run fingers across skin
and touch yourself
touching.

Data physicalization represents data in physical form.⁴ Like other approaches to understanding and representing data, it highlights particular senses to communicate information, specifically touch and sight.⁵ But data physicalization is distinct from other sensory approaches in that it bridges the gap between creative, physical, and conceptual exploration, a nexus often associated with critical making.⁶ Data physicalizations surface the amount of labor involved with data production and representation, they lend data different perspectives and dimensions.⁷ These physicalizations also create an opportunity for viewers to become active participants in the making of a piece using data.

Data physicalization attempts to defamiliarize us from the many two-dimensional data representations we have seen by literally placing data in the *mise en scène* of a conceptual exploration. There is something unique about turning data points into physical forms and placing them in space that triggers the mind to understand data in a distinctive way.

Concept map situating data physicalization in relation to other types of data representations and interpretations. Revised from the concept map included in the poster presented by the authors at DH2019 in Utrecht. Koeser, Rebecca Sutton, Nick Budak, Gissoo Doroudian, and Xinyi Li. "Data Beyond Vision," July 11, 2019.

There is an ethics of drawing on other senses. Feminist philosopher Donna Haraway describes “visualizing technologies” as the “god trick of seeing everything from nowhere.”⁸ Klein and D’Ignazio expand on this, demonstrating that the assumed neutrality and objectivity of even the simplest visualizations always come from a particular perspective, usually a dominant cultural view that fundamentally excludes and marginalizes.

This is especially the case when making data visualization accessible to vision-impaired readers. The typical solution is to provide a table with the data underlying the chart or graph. This isn’t practical for large datasets, and it’s clearly not the same experience; otherwise, we would provide the tabular data to all users. Another approach is to provide an extended description sharing the insights gained from the chart.⁹ This is helpful, but pre-digesting the chart in this way doesn’t allow readers to perceive and interpret the patterns and draw their own conclusions. Tactile data physicalizations provide sensory forms that offer individuals the opportunity to explore and discover patterns in the data for themselves.

Approaching an object like a data physicalization on display encourages bodily engagement in physical space. It encourages the person encountering it to consider multiple angles and perspectives, and it should raise questions about how the objects are meant to be read. This touching requires proximity and a certain intimacy.¹⁰ For Emmanuel Levinas, the “ocularcentrism” of western civilization has produced a false sense that vision is synonymous with objectivity; he proposes instead the metaphor of touch as the basis for ethical engagement with the Other. Ocularcentrism requires distance or separation and encourages objectification and mastery¹¹ of that which is viewed. French feminist philosopher Luce Irigaray extends this metaphor¹² in her notion of the “caress”, which “weds without consum(mat)ing”. Because touch requires intimacy, boundaries, and consent, it offers connection without the taint of mastery.¹³

S

These are not artist statements because this is not art; these objects might look like Data Art, but the goals and methods are different. This is representation, correspondence, laborious translation. These are our attempts to communicate our goals, to help you *read* and interpret these unfamiliar objects, and to be challenged by the potential of physicalization.

We invite you to participate in the embodiment and visible labor of data work. Download the following models and instructions, use your hands to recreate the data physicalizations we developed, or use them as inspiration to make your own interpretive objects. If you make any of these physicalizations, please share them on social media with the hashtag [#DataBeyondVision](#).

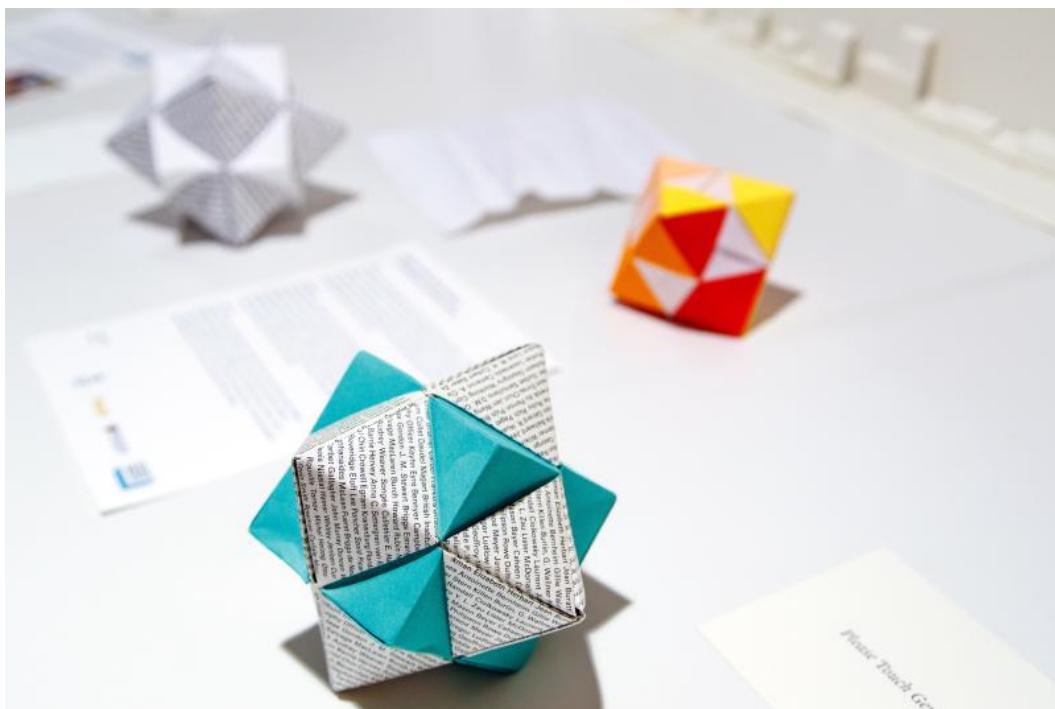

Folding in the Lesser-Known Members of the Shakespeare and Company Library

Nick Budak, Xinyi Li

Goal

The Shakespeare and Company lending library is most often known by its famous members – writers such as Gertrude Stein, James Joyce, Ernest Hemingway, Aimé Césaire, Simone de Beauvoir. We wanted to highlight the activity of the relatively unknown members – frequently women – who in fact represent a much larger portion of the library’s day-to-day activity and thus arguably better represent it. This piece makes use of unit origami¹⁴ to create a larger, cohesive form from small folded units, mirroring the relationship between a single member and the overall membership of the library.

Completed piece on display at the Center for Digital Humanities, with early drafts visible in background.

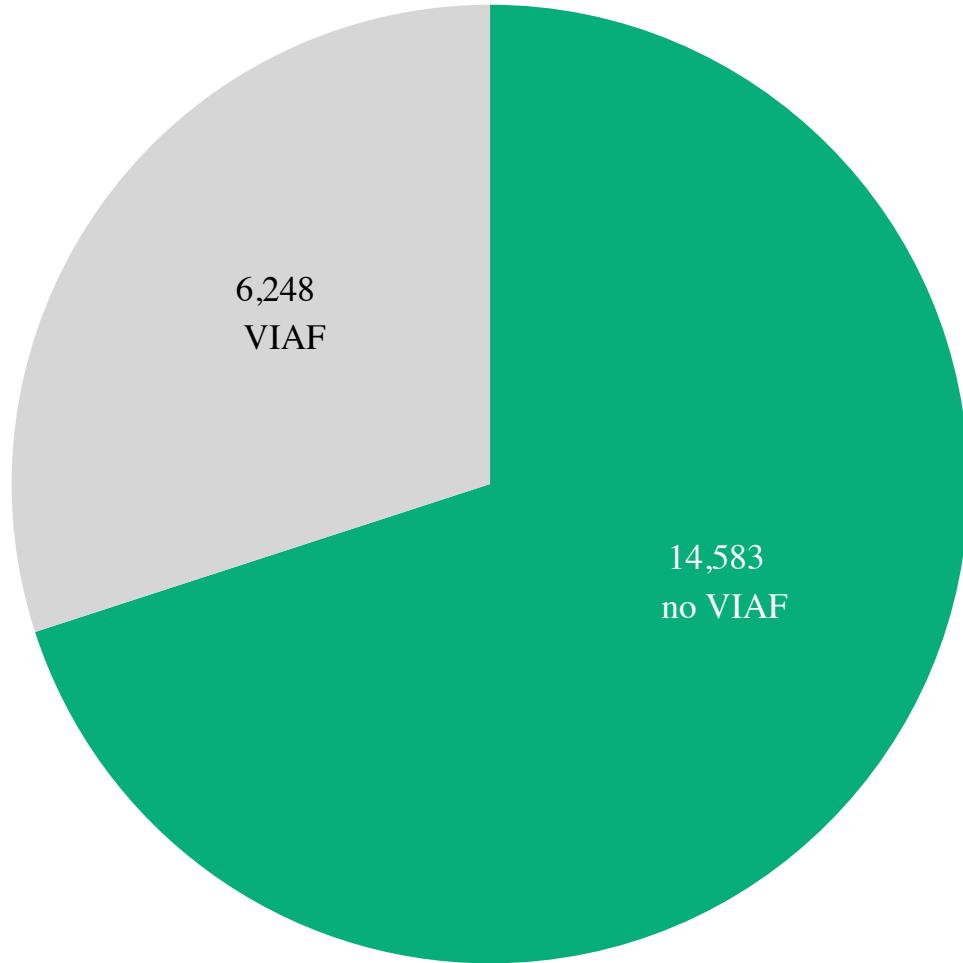

Description

The physicalization contrasts the activity of the better-known members of the lending library – those linked by researchers to an entry in the [Virtual International Authority File \(VIAF\)](#)¹⁵ – with the activity of relatively unknown members with no known authority record.¹⁶ Activity is represented by the total number of borrowing events that would plausibly have brought members into the library, namely checking out and returning books. Names of the lesser known members are printed on the paper used to create the octahedron as a way of corporealizing and “re-humanizing” humanities data.¹⁷ By holding the physicalization in two different ways, the user can “grasp” two separate sets of data: the octahedron (non-famous members) and the cube

(famous members). The ratio of the volumes of these two solids reflects the use of the library by these two different groups.¹⁸

Insights

A pie chart representing the proportions of members with and without VIAF identification.

A pie chart can be used to present the same ratio of data conveyed in the physicalization; this representation is useful when we want to illustrate a situation where we know the totality of the data. Pie charts also depict a world where data fits neatly into mutually exclusive categories. The act of grasping the two intersecting solids in our physicalization is a response to this approach: the membership data of the lending library is a work in progress, updated as researchers comb through archives that are fragmentary and incomplete. One cannot see all sides of a three-dimensional solid simultaneously. By representing our data as intersecting solids, we instead mirror the fuzzy distinction between “famous” and “non-famous” members, acknowledging the intersection of the varied identities of the library’s members.¹⁹

Next Steps

unique folding patterns for individual library member activity and make them available via print-on-demand, which would enable viewers to become participants and turn folding into an act of recovery of the stories of the lesser-known library members.²⁰

Modeling Shakespeare and Company Library Membership

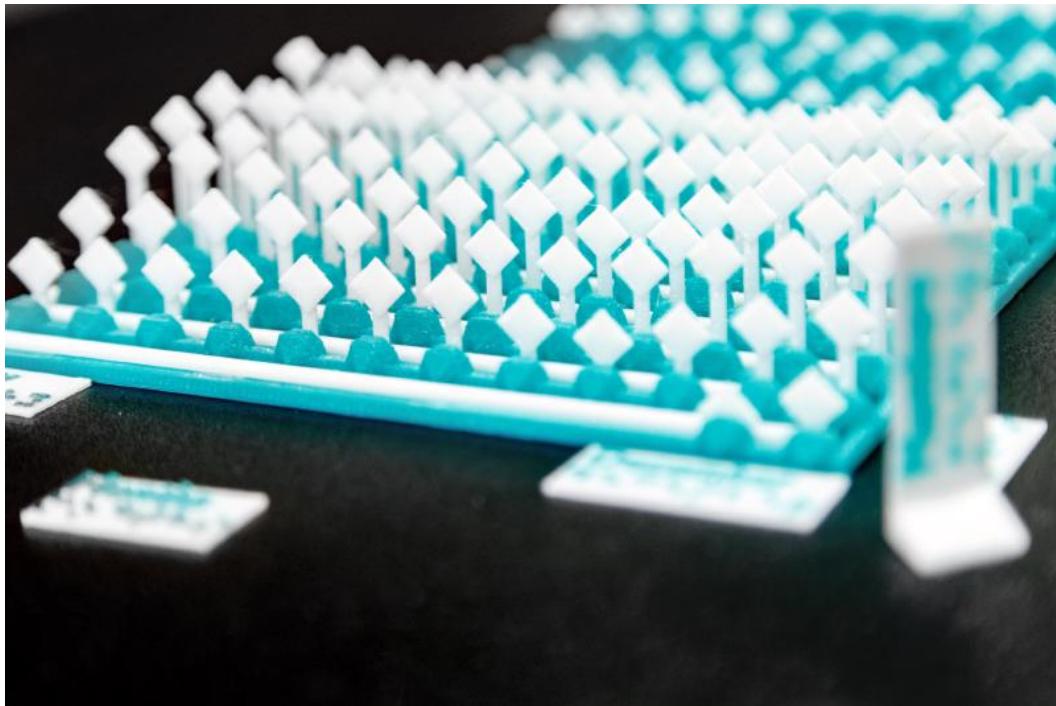

Rebecca Sutton Koeser

Goal

Side view of 3D printed lollipop chart with labels and statement.

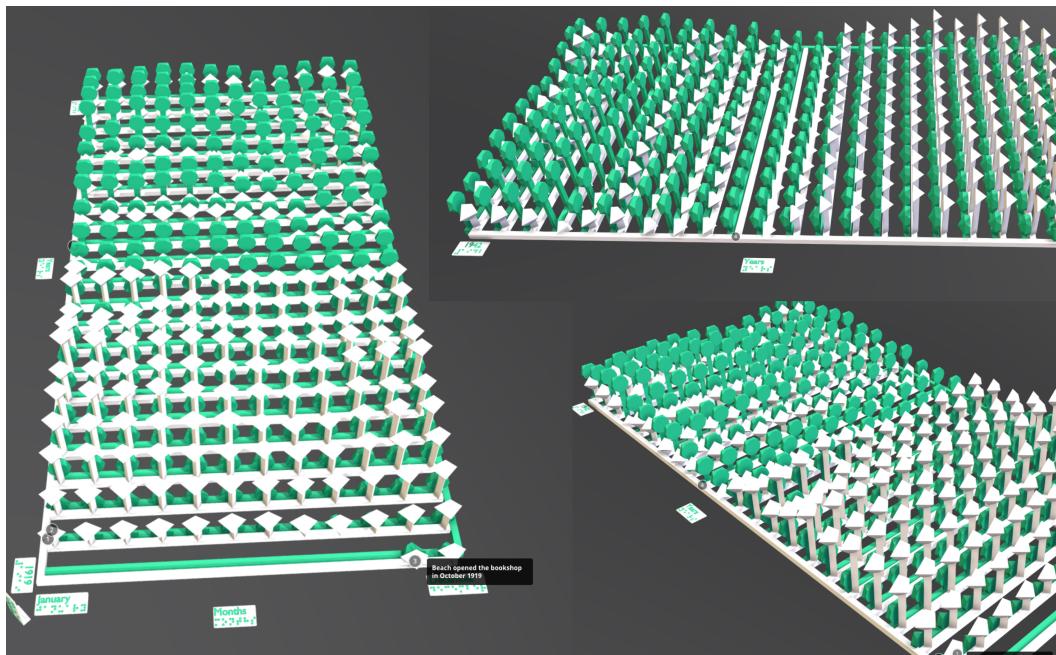

This data physicalization demonstrates the affordances of three dimensions for representing data: time series data are displayed with sequential months and years adjacent to each other, which makes it easier to discern seasonal and annual trends. I hope to inspire others to try experimental approaches to representing data; writing software to generate printable 3D models directly from the data makes the process reproducible, and may eventually enable others to create and print their own physicalizations. The tactile nature of the object suggests the possibilities of 3D printing to create more accessible representations of data.

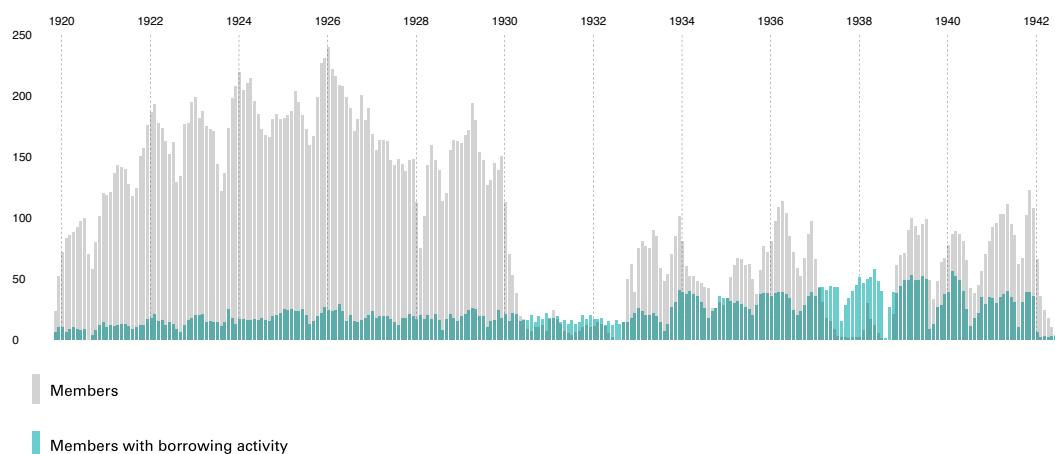

Close up of 3D printed lollipop chart with labels.

Description

This is a two-variable, three-dimensional lollipop chart²¹ showing the membership of the Shakespeare and Company lending library, by month and year, from November 1919 when Sylvia Beach opened her bookshop to its official closing in 1941. Membership data is drawn from two different sources, both of which are incomplete: broad membership information comes from [logbooks](#) (although logbooks for 1930, parts of 1931-32, and 1937 are missing); detailed borrowing histories come from [lending library cards](#) for a subset of members.²² The white octahedrons represent the number of members with an active membership in each month; the green icospheres²³ correspond to the number of members with borrowing activity in each month. For any month where the value is zero, there is no lollipop. Representing the two different datasets as adjacent, half lollipops exposes the discrepancies between the stories these sources tell us about the membership of the library without privileging either of them.²⁴ Using two different shapes makes the two parts of the physicalization distinguishable to touch. The two lollipop charts are designed to be printed independently and then assembled, so that any 3D printer can be used. In this version, the two pieces slide together; this is both a simplification and an improvement over the previous version, where one piece was placed on top of the other.²⁵

Insights

Shakespeare and Company lending library members with borrowing activity and members, 1919–1941.

From Kotin and Koeser, “The Shakespeare and Company Lending Library Cards in Context.”

<http://shakespeareandco.princeton.edu/analysis/2020/03/shakespeare-and-company-lending-library-cards-context/>.

The same membership data can be presented in a two-variable bar chart. Overall trends are easy to see, and both representations of the data make it possible to compare the two data series against each other. Seasonal trends are visible in the bar chart, but it's difficult to identify distinct months; in contrast, changing perspective on the 3D lollipop chart allows focusing on yearly or monthly trends. Missing data in one variable is visible in both, but seems more striking in the 3D version where the base of the piece is bare without any lollipop tops. At the current scale, touching the piece requires focusing attention on just a portion of the object but invites

exploration, which can proceed in any direction.²⁶ While the bar chart demands sequential reading from left to right, the 3D printed object doesn't provide or demand a particular starting point or sequence.

The bar chart conveys a sense of certitude and exactness that does not reflect the missing and partial data that underlies it; the 3D printed object, with its irregularities and fragility, is more representative of the contingent, historical data.²⁷

Next Steps

The current version uses different shapes for the two variables, but adding textures would make the model even more tactile. Simple 3D printed labels with text and braille²⁸ have been added for display alongside the piece, but they could be incorporated directly on the model, and refined to provide a scale for the axes. The 3D printed objects could also be augmented with other media: lights or sound could convey the intensity of borrowing activity, or threads connecting months to represent the number of subscription renewals and convey a sense of continuity. The Python code used to create these models could be generalized for reuse, and eventually made available as a Blender plugin.²⁹ New shapes or approaches could be used to leverage innovations in 3D modeling, such as generative design, to create objects that are more inviting to touch and even more distinct from 2D data visualizations. 3D models could be revised for fabrication with CNC machines to create objects out of wood instead of plastic, which could make them more inviting to touch.

Weaving Derrida's References

... we all of us, grave or light, get our thoughts entangled in metaphors...

– George Eliot, Middlemarch

Rebecca Sutton Koeser, Gissoo Doroudian

Goal

With this piece, we aim to literalize the metaphor of weaving as writing, embedded in the very words textile and text³⁰, by representing Derrida's intertextuality as a woven tapestry. The textures of the yarn and woven fabric invite touch, but by showing an in-progress weaving with the pattern and instructions provided, we move viewers beyond seeing and touching to enable them to become participants in reconstructing the data. Showing the weaving in progress also foregrounds the labor of data work, since curation, collection, and visualization all take an enormous amount of work and skill, often from a range of different individuals.

The online version of this essay includes an interactive deep zoom viewer displaying a high resolution capture of this object.

Description

This weaving represents the references in chapter one of Jacques Derrida's *de la Grammatologie* (1967). The references have been cataloged and categorized by the research team of Derrida's Margins.³¹ Each type of reference (epigraph, citation, quotation, footnote) is represented by a distinct yarn and weaving pattern. Derrida's highly intertextual writing suggested the idea of weaving.³² Using yarn to symbolize the foundational work of deconstructionism, which operates by finding the place where a text unravels, gives additional depth to this physicalization.

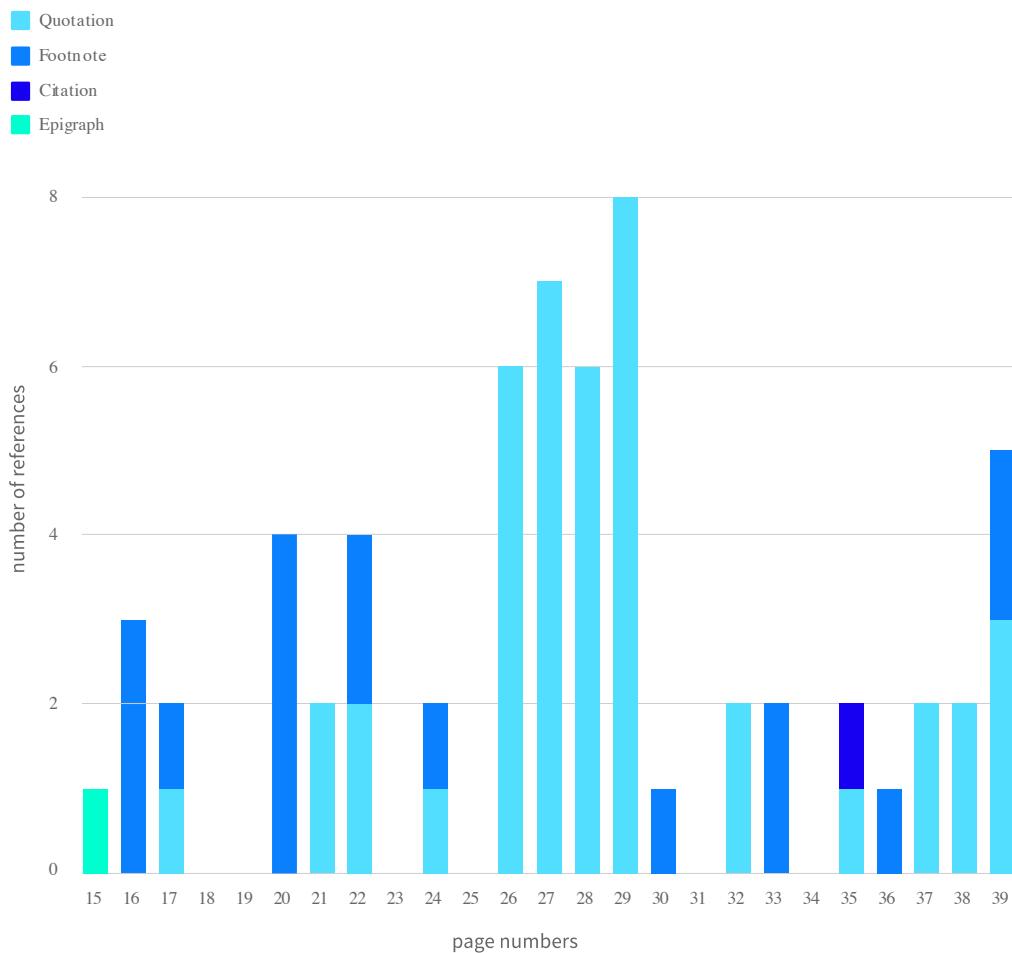

Working with textiles is often stereotyped as female activity, therefore this piece also raises questions of gender and other false binaries such as art versus craft, high and low tech. Based on anthropological research, women produced most of the textiles in the ancient world, but that work can be read as female authorship involved in the earliest textual practices.³³ The loom itself runs the gamut from high and low technology: a backstrap loom can be assembled at home from dowels, rods, and cords; and yet, Joseph-Marie Jacquard's 1801 power loom, which used punch cards to automatically create elaborate woven patterns, was an important precursor to early computers.

Gissoo, creating a Soumak weave.

Insights

The data encoded in the weaving could be represented as a stacked bar chart, a familiar and easily available choice for communicating types and quantities. However, it may be the least effective for communicating the depth and conceptual nuance of data on multiple levels.

References in chapter 1 of Of Grammatology by page and type. (Chapter 1 begins on page 15).

The ability to feel the density and frequency of each type of reference, color coded above, creates a unique experience for each participant, specific to their own perspective. These organic experiences bring to light the depth and complexities of the original work as well as the labor involved with gathering this data. This woven piece, which represents the first half (thirteen pages) of the first chapter of *Of Grammatology* is 37 inches long, a little more than 3 feet. The physical nature of this data representation required that materials and dimensions be carefully calculated and measured.³⁴ The process of creating this piece is embodied and experiential, which naturally leads to conversations that effortlessly surface the labor of data work and the depth of the original text. Unfortunately, this is less likely to happen naturally when creating data visualizations.

Next Steps

Adding conductive thread and sensors could turn the weaving into an interface, so that touching the fabric would bring up the relevant reference on an associated screen. Data weavings could also be augmented with other media, such as lights and sound to convey other aspects of the same or related data. Incorporating other work on automated weaving and knitting machines would add to the variety of options for data textiles.

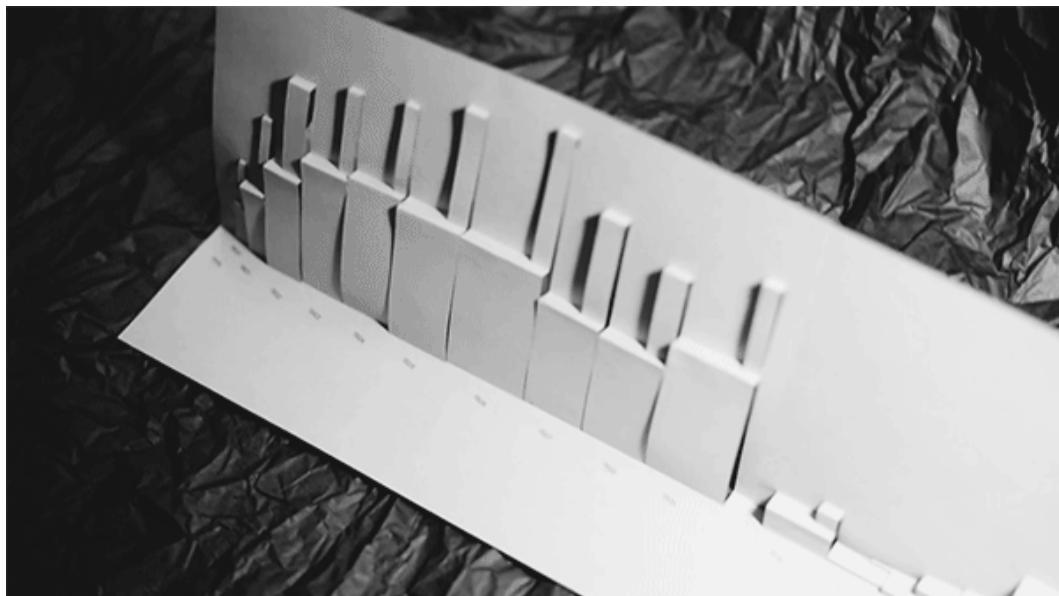

Stacking New and Continuing Membership Activities of the Shakespeare and Company Lending Library

Xinyi Li

Goal

This piece aims to reveal the continuity and growth of Sylvia Beach's lending library by showing the extent of activity and recorded membership based on logbooks and lending library cards. Multiple variables are encoded in the dimensions of stacking boxes based on the technique of pop-up box folds. By exhibiting the evolution of the library over time while contrasting activities of new and old members, this piece enables multiple ways to compare and interpret the data from diverse perspectives. By transforming a flat surface to a three-dimensional form with play of light and shadows, this production technique serves as a metaphor for the larger purpose of the [Shakespeare and Company Project](#) – bringing archival data to life and facilitating rich interpretations.

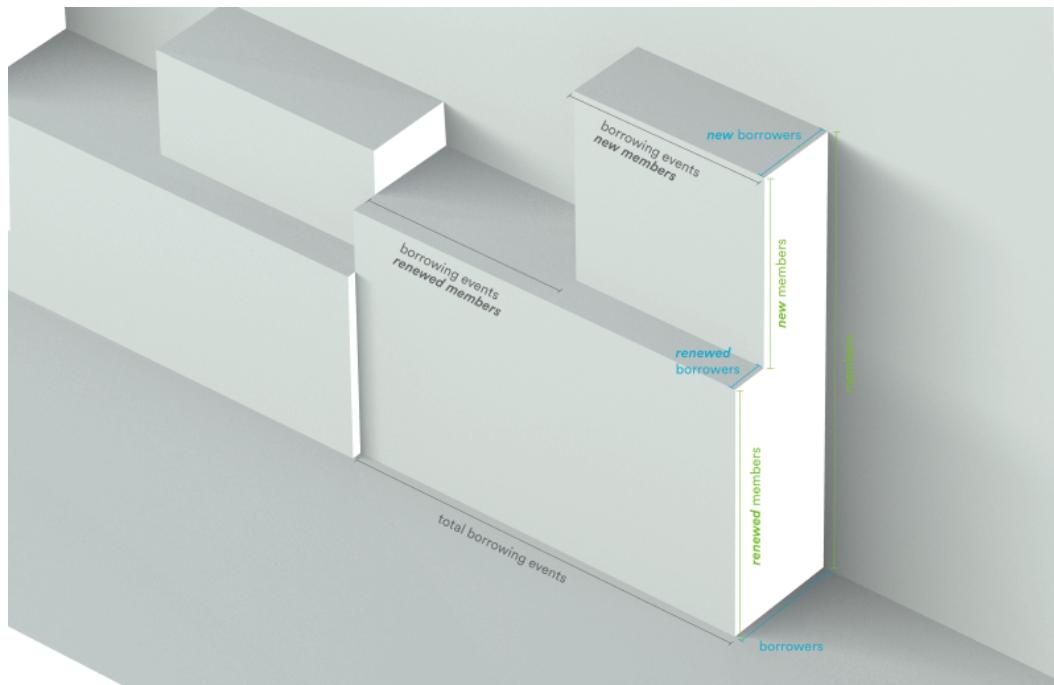

Overview of a folded model representing the lending library membership activities from 1919–1941.

Description

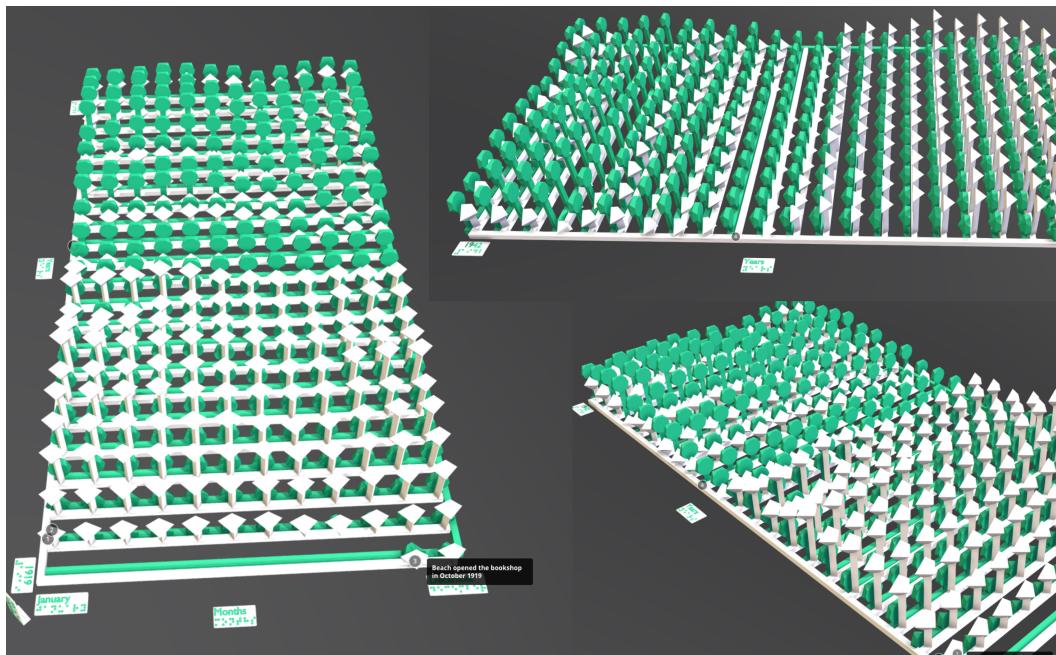

[Shakespeare and Company Project](#) lending library membership data from 1919 to 1941 are represented as a hybrid of time-series and stacked bar charts showing part-to-whole relationships made from paper and folding. Each unit, a cuboid in space and sometimes its stacking child, represents one year and displays nine variables for that year. The height corresponds to the number of active members recorded in the [logbooks](#); the depth depicts the number of members with borrowing activity, according to each member's [lending library card](#); the length along the timeline is based on the total number of borrowing events.³⁵ Each of the

variables is split into two parts: previous members who have renewed a membership contrasted with new members. The upper portion shows the growth and the activities of new readers. Viewers can see the rise and fall of members, inspect the difference between members with borrowing activity and the members as represented in the logbooks, compare the growth over time by viewing the stacking part from the front, and survey the involvement of continuing members versus new members, to name a few possibilities. In some cases, a small number of new members were very active readers based on their borrowing activity.

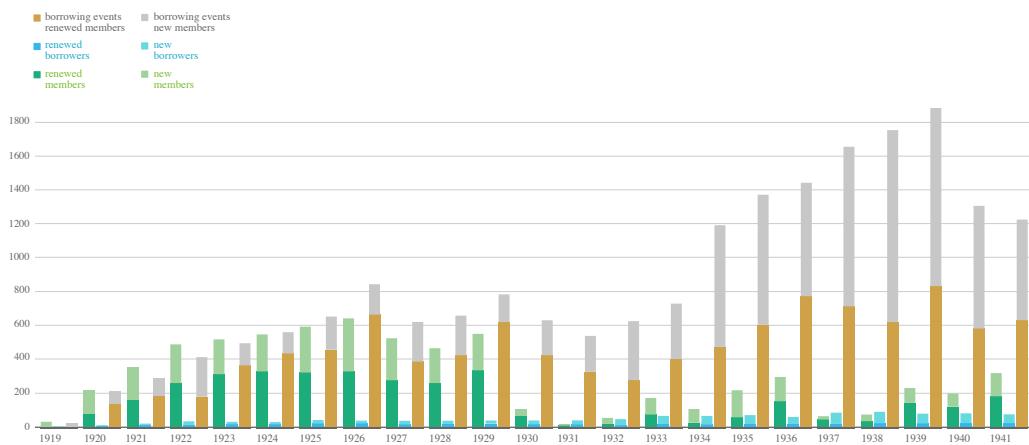

Legend showing how to read the information represented in three dimensions.

This physicalization made use of kirigami technique, which transforms single sheets of paper into three-dimensional forms. Data was mapped to the shapes with [Data Illustrator](#), semi-manual calculation, and vector drawing. The materiality and the process have a poetic connection to the subject matter, metaphorically: stories and knowledge can be embedded on flat papers, but the act of reading unfolds the surface into interpretive space even beyond three dimensions.

The online version of this essay includes an interactive 3D viewer displaying a model of this object.

Insights

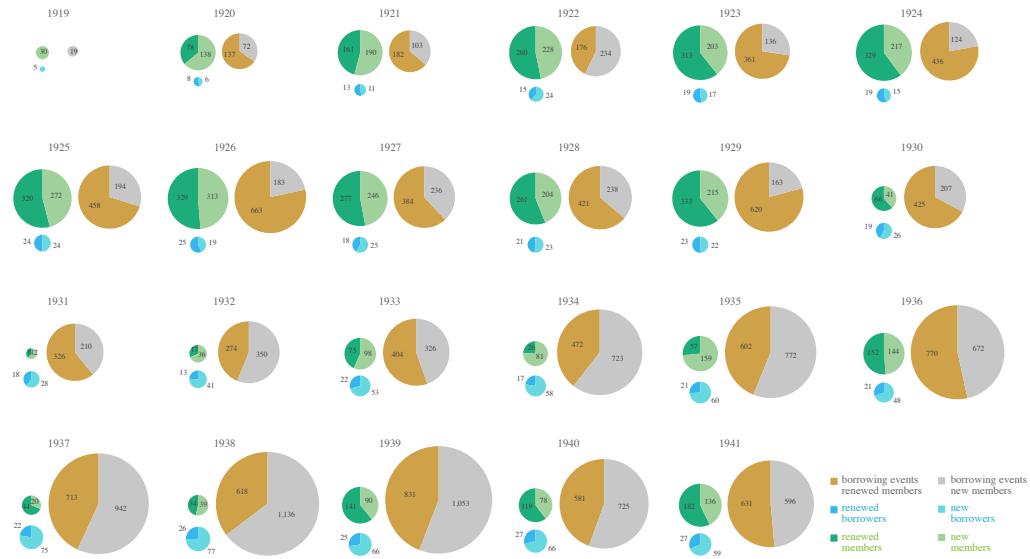

Membership activities of Shakespeare and Company Lending Library from 1919–1941 represented as stacked bar charts.

With current off-the-shelf visualization tools like the ones that come with Google Sheets, these three data series can generate three separate stacked bar charts. Since the numbers have different ranges, the vertical axes are drawn in different scales, which makes comparison across series impossible. The aggregate version presented here required manual adjustment to combine the separated charts and to make the Y axes comparable. In this 2D version, various

activities of the growing membership body are not linked, and it's difficult to draw connections between active members and the intensity of their activities because spatially these bars are not adjacent to each other. In the conventional pie charts, although the part-whole relationship between new membership activity and all activity is apparent, comparing across the three types of activities is not possible.

Membership activities of Shakespeare and Company Lending Library between 1919 and 1941 represented as pie charts.

Extending into physical space allows data to be encoded in three axes and provides multiple possible angles to view the piece, depending on the relationships one is interested in, between logbook members, members with lending library card activities, and borrowing events. The separation of renewing and new members makes it possible to juxtapose and compare activities between the two groups of members. Spatial factors communicate different facets of the data, and color coding is no longer required.

Throughout the process of developing this project as practice-based research, making and reflecting are in constant oscillation, and knowing happens in actions. As I worked through this piece and observed the artifact, new questions emerged: how do we measure the level of liveliness of the lending library? Is it by the number of members or by the number of borrowing events? Instead of drawing comparisons by the lengths along each axis, perhaps this physicalization also introduces another way to look at the vibrancy of the lending library: through the volumes and relative sizes of the cuboids and rectangles, which factor in both the number of members and the borrowing activity.

Next Steps

The pattern generation process is very programming-friendly and the materials required are also easily accessible. The data encoding process could be automated by custom code, which could then be made available as a tool for presenting part-to-whole relationships in other data sets. With the addition of dynamic media such as projection mapping, this piece could convey more context and narratives around the lending library.

17. This is inspired in part by ethical principles from the Colored Conventions Project, which asks researchers using their data to “contextualize and narrate the conditions of the people who appear as ‘data’ and to name them when possible.” <https://coloredconventions.org/about-records/ccp-corpus/> ↩

18. We wanted to include a 3D model of this physicalization in order to provide some semblance of virtually grasping and rotating the object. Because we didn’t have a way to capture the actual object in 3D, we created a model of it in Blender; this was fairly straightforward, since it consists of two simple shapes. ↩

19. For more on the strengths and weaknesses of the pie chart, see Johnson, Steve. “The Case Against Pie Charts,” March 3, 2017. <https://accelerate.uofuhealth.utah.edu/connect/steves-dojo-7-the-case-against-pie-charts> ↩

20. We do not provide a how-to for this object out of respect for the copyright of origami authors, who often spend years developing and refining single designs. The three-dimensional forms used to make this piece are a combination of two modular origami units which are the original creations of the brilliant Tomoko Fuse, and can be found in her book *Unit Origami: Multidimensional Transformations*. The octahedron is formed from eight units with triangular windows (p. 109), and these windows are filled with eight so-called E-b units (p. 233) that create the illusion of an intersecting cube. When assembling from your own paper, you can print [a](#)

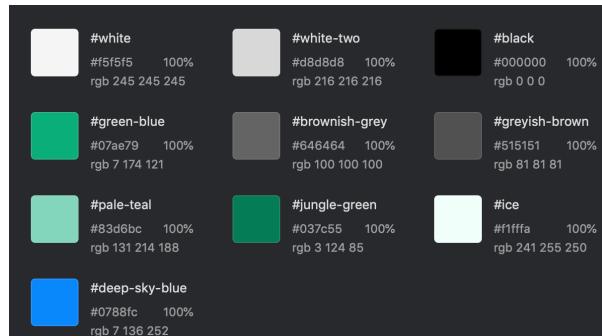

document containing the names of the non-VIAF members of the library onto the paper before folding the octahedron. Sheets of 8.5" x 11" copy paper can become difficult to manipulate when folded many times; thinner paper is easier to work with. ↵

21.A lollipop chart is a bar chart variant that uses dots to mark the values. Earlier prototypes of this model were based on bar charts, but I discovered that the space between bars in a lollipop chart made it easier to “read” the 3D version, since they obscure less of the model visually. ↵

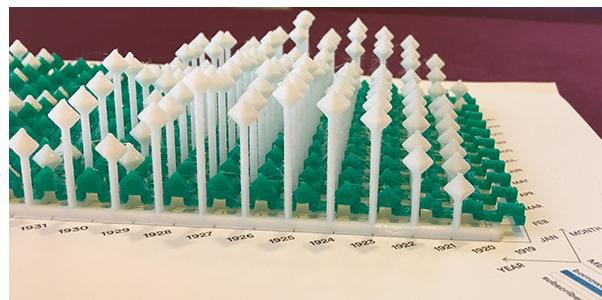

22.This work is based on pre-release versions of the datasets now available. Kotin et al., Shakespeare and Company Project Dataset: Lending Library Members, Books, Events, <https://doi.org/10.34770/pe9w-x904> ↵

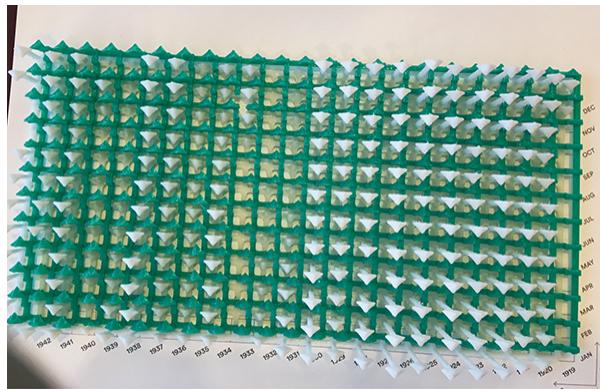

23.We use white and green in our physicalizations of data from the Shakespeare and Company Project because green is the most iconic color used in the site design.

24.To better understand the Shakespeare and Company Project sources, read: Shakespeare and Company Project. “Lending Library Cards.” Center for Digital Humanities, Princeton University, November 20, 2019. <https://shakespeareandco.princeton.edu/sources/cards/>; and Shakespeare and Company Project. “Logbooks.” Center for Digital Humanities, Princeton University, November 20, 2019. <https://shakespeareandco.princeton.edu/sources/logbooks/>. To understand how the Project data from those sources fit together, read Kotin, Joshua and Rebecca Sutton Koeser. “The Shakespeare and Company Lending Library Cards in Context.” Shakespeare and Company Project, version 1.2.3. Center for Digital Humanities, Princeton University. March 9, 2020. <http://shakespeareandco.princeton.edu/analysis/2020/03/shakespeare-and-company-lending-library-cards-context/>. ↵

25.The previous version was more complicated to print; the overlapping framework interfered with small data points, and the tightly interlocking parts did not scale well.

↔

26. Due to COVID-19, I'm writing and revising this from my home office without physical access to the object in question. I find myself closing my eyes and extending my fingers to focus on my memories of touching the object. ↔

27. For an exploration of the subjectivity, uncertainty and interpretation implicit in data, read Rebecca Munson's essay in this issue of *Startwords*. "Visualizing the Uncertainty in Data." *FlowingData* (blog), January 8, 2018. <https://flowingdata.com/2018/01/08/visualizing-the-uncertainty-in-data/>. For more on the difficulty people have in recognizing uncertainty in data visualization, see D'Ignazio and Klein on "Visceralizing Uncertainty" in *Data Feminism*, p.88. ↔

28. These have not yet been tested by anyone who reads braille. ↔

29. Blender is an open source 3D modeling creation suite which includes a Python API. I experimented with multiple other solutions for generating 3D models programmatically, including OpenSCAD and Tangible, but found they were too limited and couldn't handle the size of model I needed to generate for this dataset, so I eventually settled on Blender and Python. The blender interface makes it possible to view and modify models generated from code, there is documentation for the Python API, and I found many helpful answers on Blender Stack Exchange. ↔

30. The word "text" comes from Latin *textus*, literally "thing woven" and from the verb *texere*, "to weave." According to Kathryn Sullivan Kruger, "the connection between weaving (textiles) and language (texts) becomes so entangled as to be almost impossible to separate. In many languages, including English, the verb to weave defines not just the making of textiles, but any creative act." (from *Weaving the Word: The Metaphorics of Weaving and Female Textual Production*, 2001). To play on one of Derrida's most famous statements, "il n'y a pas de hors-textile." ↔

34.When we first did the math on the weaving and measured, we discovered that doing all of chapter one would require a warp longer than three tables end-to-end in the CDH main space, which is why we scaled back to just half of the chapter.
